Towards the Total Synthesis of the Tetranortriterpene Gedunin

Craig Williams

University of Queensland, Brisbane, Qld, Australia

Gedunin (1), which was first isolated from the West African timber Entandrophragma angolense in 1960, has been reported to exhibit a diverse range of biological activities, including antimalarial, antifungal, allergic response, peptic ulcer, anti-cancer, eryptosis, antifilarial, and insecticidal activity. In terms of anticancer activity, however, gedunin (1) was explored through the use of a connectivity map, and found to exhibited antiproliferative activity through the heat shock protein Hsp90. Such compelling biological interest in this compound inspired our group to investigate a synthetic route to gedunin so as to open opportunities for better understanding the underlying biochemical pathways. The lecture will describe our efforts in achieving the construction of a key advanced intermediate and subsequent activities towards total synthesis.
